Q1

1. Estimate its HOMO-LUMO energy gap using the particle-in-a-box model.

Command: b3lyp/6-31g(d) pop=(nbo,savenbos) geom=connectivity

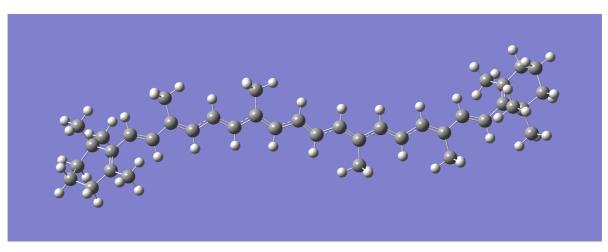

After the implementation of particle in a box model, I get the molecule orbit as follows.

NBO index	Molecular units	Energy(Hartree)	Class
148	CR (1) C 40	-0.024560	НОМО
149	RY*(1) C 1	0.05938	LUMO

Consequently, the HOMO-LUMO energy gap is 0.08394 Hartree

2. Obtain its stable structure using a proper quantum mechanical method and briefly

describe the structure.

Command: opt=calcfc b3lyp/6-31g(d)

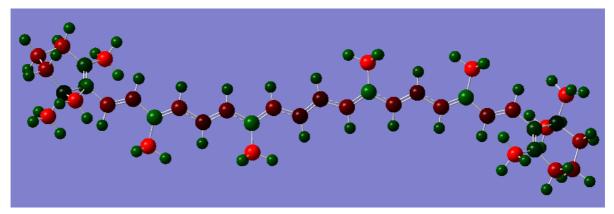

In this case, I choose B3LYP and 6-31G(d) as the calculation parameters. And after 13 steps, the total energy converge at around -1557.9 Hartree. Indicating the normal termination of optimization precess. The description of the optimized molecule

Beta-carotene, with the molecular formula $C_{40}H_{56}$, owns a long chain of conjugated double bounds together with two retinyl groups. The huge conjugated structure equip this molecule of highly-delocalized electron groups.

As the picture describes, there are up to 40 electron pairs locate in a same energy level, illustrating the delocalization of the electrons.

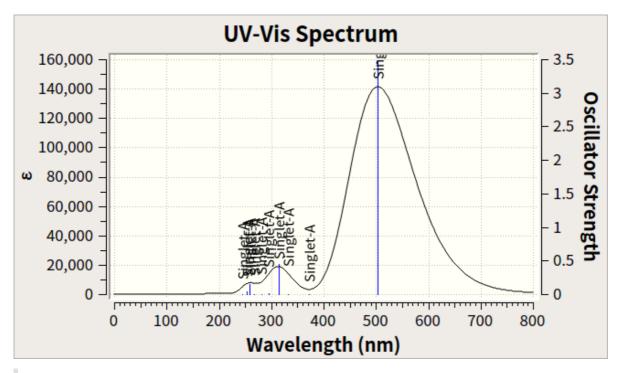

The distribution of charge and bonds' length also prove the delocalization of electrons. As is shown in the figure, the charge of the central chain goes through a sort of equalization, which also happens in the bond length.

Class	Typical Bond Length(pm)	Typical Bond Order
Ethylene	(C=C) 133.9	2
Ethene	(C-C) 152.8	1
eta-Carotene	(C=C)137.4 (C-C) 144.3	(C=C)2 (C-C)1.5

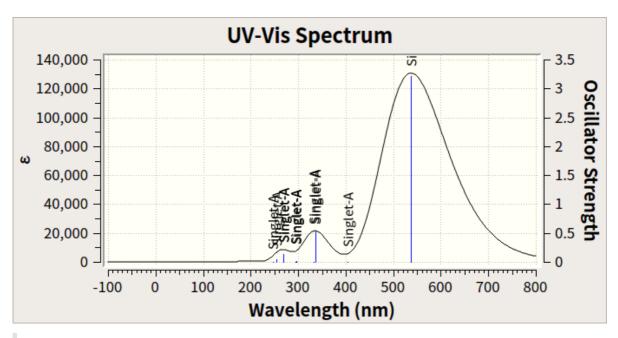

3. Based on the structure obtained in step 2, compute its UV-Vis spectra in the gas phase, using the ZINDO method (nstates=10).

Command: zindo=(astates=10)

4. Re-compute its UV-Vis spectra in ethanol using the same method with the IEFPCM solvation model

Command: zindo=(nstates=10) scrf=(iefpcm,solvent=ethanol)

5. The experimentally measured maximum UV-vis absorption peak in ethanol is 450 nm. Discuss all the computed and the experimental excitation energy values and comment on

The calculated excitation by ZINDO model get an excitation energy of c.a. 540 nm. Frankly speaking, the gap between the experimental and computed data is not even far.

Consequently, i would like to have some discussion about the significant gap. As long as solvation model, compute model and molecular itself are considered, I hold the opinion that the *IEFPCM* solvation model and $\beta-Carotene's$ own properties contribute to the bias. I will elaborate my stand from two aspects ---- the model and the solvent molecular.

First, the IEFPCM solvation model itself plays an important role in generating the bias. An implicit solvent model as it is, it fails to deal with non-electrostatic components in the given situation, which means the hydrogen bond existing in the system can not be take into consideration. Nevertheless, hydrogen bonds contribute significantly to the molecular conformation in polarize environment, in this case, the ethanol. The conformation will then have impacts on the conjugate structure, which mainly provides $\pi \to \pi^*$ transition, and the UV-Vis spectrum as well. Second, the $\beta-Carotene$ molecule generate UV-Vis absorption by the $\pi \to \pi^*$ transition. But according to the solvent effect upon the UV-Vis spectrum, polar solvent will leads to a phenomena called "Red shift" on the $\pi \to \pi^*$ transition which means the absorption peak will shift to a higher position, from 450 nm to 540 nm.

Then i want to have some comments on the ZINDO model.

• As for the efficiency, ZINDO's semi-empirical type shows higher speed in calculation than those *ab initio* methods such as TDDFT. I calculate in both means and make a compare.

TDDFT: Job cpu time: 0 days 19 hours 33 minutes 11.0 seconds.

ZINDO: Job cpu time: 0 days 0 hours 4 minutes 20.8 seconds.

• As for the accuracy, ZINDO's mechanism ----**INDO** method guarantees the accuracy of spectrum calculation.

TDDFT: Absorption peak: 600 nm

ZINDO: Absorption peak 540 nm

Q2

###

1. Using the 6-31G(d) basis set, determine the transition state for the dehydration of ethanol to ethylene, and record the B3LYP/6-31G(d) and MP2/6-31G(d) values for the barrier height.

After calculation i have got the possible transition state. Both states have only one imaginary frequency. And the imaginary frequency suits the procedure of the reaction. Hence we can make sure that these transition states are the exception state. According to such a formula:

$$E_{barrier} = E_{trasition} - E_{reactant}$$

We can get the barrier energy of this reaction.

DFT Method: 293.73kJ/mol MP2 Method: 320.71kJ/mol

2. IRC Path

Q4

1. Guess the structures

Molecule C_4H_4 ,with a degree of unsaturation $\Omega=4$, is likely to contain unsaturation bonds within the molecule. The question mentions several frequencies, and I just started some analysis.

- ullet 215 cm^{-1} **s** Have not found any specific indication, but might refer to conjugate structure
- $852cm^{-1}$ **s** This absorption peak indicates CH_2 wagging
- $1608cm^{-1}$ **s** This absorption peak indicates CC stretching

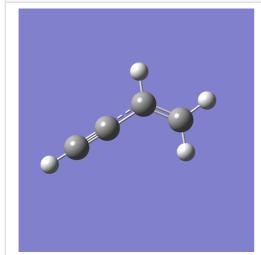

•

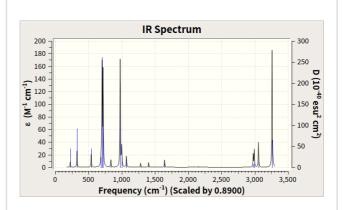

2&3. Optimize the lowest singlet states

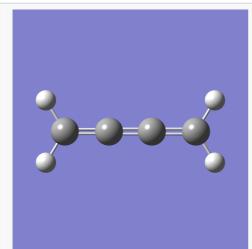

After some calculations, I pick up 4 candidates for this question. They are listed as follows.

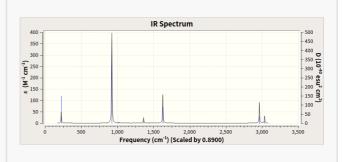

Structure

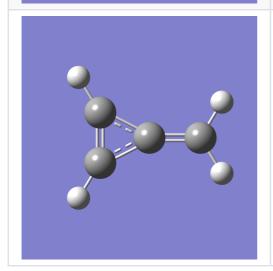

IR Spectrum

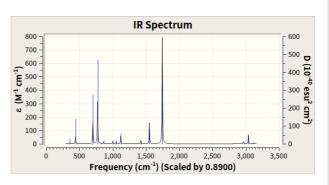

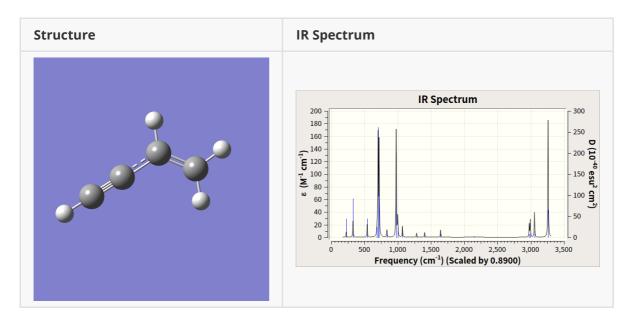

4. Discussion upon the structure

Q5

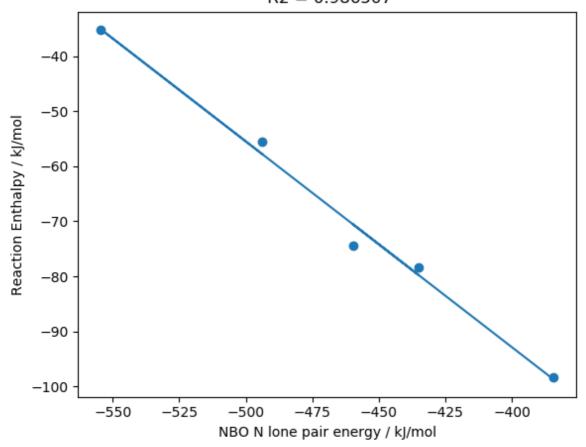

1. Compute the reaction enthalpy

Class	Before Hartree	After Hartree	Reaction Enthalpy kJ/mol
Pyrr	-209.573293	-398.242577	-98.3
Pyra	-225.627079	-414.286986	-74.5
Imi	-225.652388	-414.313914	-78.3
Tria123	-241.686778	-430.331907	-35.2
Tria124	-241.710414	-430.363153	-55.5

2. N lone pair energy

Class	Bond Index	Bound Energy (Hartree)	Electron distribution and Energy level

Tria124	15	-493.882805	24 — 0.70242 25 — 0.70246 22 — 0.60541 23 — 0.60541 24 — 0.50572 26 — 0.50064 25 — 0.50764 27 — 0.50762 26 — 0.50764 27 — 0.50766 27 — 0.50764 27 — 0.50765 28 — 0.60691 29 — 0.50691 20 — 0.50691 20 — 0.50691 20 — 0.50691 20 — 0.50691 21 — 0.50692 21 — 0.50692 22 — 0.50692 23 — 0.50692 24 — 0.50693 25 — 0.50693 26 — 0.60691 27 — 0.50693 28 — 0.50693 29 — 0.50693 20 — 0.50693 20 — 0.50693 20 — 0.50693 20 — 0.50693 20 — 0.50693 20 — 0.50693 20 — 0.50693 20 — 0.50693 20 — 0.50693 21 — 0.50693 21 — 0.50693 22 — 0.50693 23 — 0.50693 24 — 0.50693 25 — 0.50693 26 — 0.50693 27 — 0.50693 28 — 0.50693 29 — 0.50693 20 — 0.

Reaction enthalpy verus N lone pair energy R2 = 0.986507

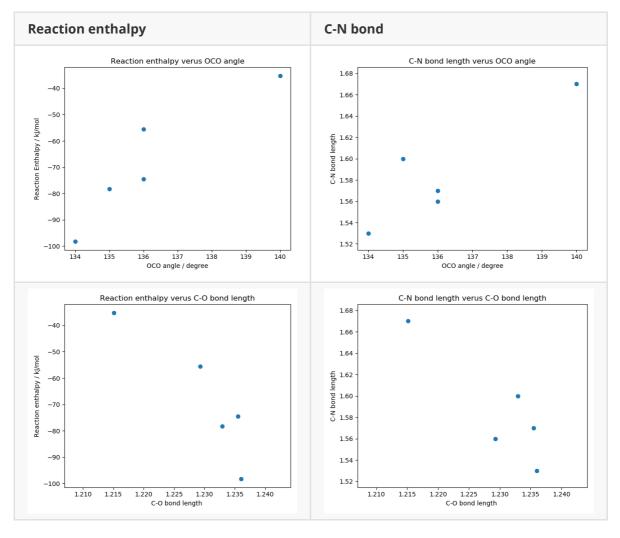

3. Discuss the geometry change of CO_2 and its reactivity with azole anions

The geometry of CO_2 consists of two parts: the $\angle OCO$ angle and d_{C-O} . In my opinion, the $\angle OCO$ will have supervise impact on the

After the calculation, I have got some data of CO_2 geometry and its reactivity.

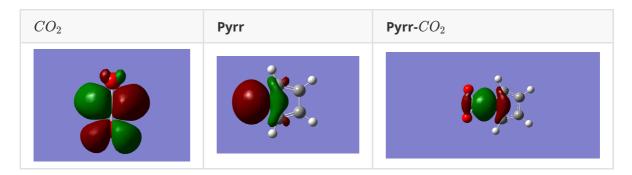

Class	d_{C-N}	∠OCO	d_{C-O}	Reaction Enthalpy
Pyrr	1.53	134	1.23603	-98.3
Pyra	1.57	136	1.23550	-74.5
Imi	1.6	135	1.23295	-78.3
Tria123	1.67	140	1.21512	-35.2
Tria124	1.56	136	1.22928	-55.5

Here i choose $\angle OCO$, d_{C-O} to represent the geometry change of the CO_2 molecule, and choose the bond length between carbon and nitrogen atom and reaction enthalpy as the measurements of the reactivity. And I get such graphs.

From these graphs we can make further assumption, the more the $\angle OCO$ bends , the higher the reactivity will be. The more the d_{C-O} stretch, the higher the reactivity will be. It 's a funny phenomena that deserve some discussion.

I want to discuss this question by Frontier molecular orbital theory. Take pyrr into consideration, the frontier of the reaction are

To generate more stable bond, which is σ_{N-C} bond in the Pyrr- CO_2 , the CO_2 molecule should bend to a proper angle to get its π_{C-O}^{\star} orbit maximum overlap with the N-lone pair orbit. And this kind of bend depends on the N lone pair's energy. The higher the N lone pair's energy, the easier it would bend the CO_2 molecule to reach stable state. The larger degree carbon dioxide bends, the more stable molecular will form. After the binding of the C-N atoms, newly constructed molecular conjugate structure will then shorten the CO_2 bond length by conjugative effects. Hence i can have more faith on my assumption that the $\angle OCO$ is the main components of the carbon dioxide's reactivity with azole anions, the length of C-O is just a consequence of forming a molecule ,which is also a consequence of $\angle OCO$ bends;

But when cast our sight into both molecules, we will find another problem. A same $\angle OCO$ might have a reaction enthalpy gap, for instance Pyrr and Tria124. Then i find that the more N atoms existing on the ring, the higher the reaction enthalpy will be. And the effect of the N number is far meticulous that the effect from angle bends in carbon dioxide. I would like to make a assumption that the bigger electronegativity leads to a dispose of electron density in the ring, which will then deactivate the reaction But there are just few molecules and data so i can not illustrate my assumption. I will try to make some further discussion after reaching more data.
